Manuscripts, such as Babad Tanah Sunda, Babad Tanah Djawa, especially, views3 download. 4 Worsley, Babad Buleleng, pp. 112.8 6 P. S. Sulendraningrat, Babad Tanah Sunda/Babad Cirebon (Cirebon: np.Å . GFR from 43.8% to 55.5% and from 70% to 73.3%, respectively. GFR can be estimated by four MDRD formulae: CKD-EPI, MDRD (with or without correction factor), Barr's and Cockcroft's. The CKD-EPI is recommended as the best prediction equation for GFR estimation. If GFR is between 30–60 mL/min, the Cockcroft's formula is also usable. If GFR is less than 30 mL/min, the MDRD formula (with correction factor) should be used. The MDRD formula is not recommended for patients with CKD stage 5 or acute dialysis. The best correction factor for alkaline phosphatase in chronic renal failure is 1.0 in men and 1.2 in women; the correction factor is 1.5 if ALP is > 2.5 times the upper limit of normal. Discussion The present systematic review demonstrates that despite strict prevention policies and increasing infection control protocols, HIV-related infections have remained a major cause of hospital admissions and a risk factor for death in HIV-positive patients. Even if pulmonary disease is the main cause of death in this population, cardiovascular disease (44.6% of death cases) is the main cause of death, accounting for 20.4% of all-cause death. HIV-related pneumonia, which is the main cause of death, is an AIDS defining condition. On the other hand, prevention efforts are well implemented on the screening of HIV-positive patients for AIDS-defining diseases, and virological monitoring. In addition, the introduction of HAART therapy for HIV-positive patients has increased survival. Hence, a decrease in AIDS-related deaths and an increased survival time of HIV-positive patients is expected. The goal of antiretroviral therapy (ART) for
